ABSTRACT

Simon Game

The Simon Game is a memory-based interactive web game developed using HTML, CSS, and JavaScript. The objective of the game is to test and improve the player's memory by displaying a sequence of colored buttons that the player must repeat in the correct order. The game begins when the user presses any key, after which a random color flashes on the screen. With each successful level, a new random color is added to the existing sequence, making the game progressively more challenging.

The application uses HTML to create the game interface, CSS to design the colorful buttons and visual flash effects, and JavaScript to handle game logic, random sequence generation, user input, score tracking, level progression, and game reset functionality. If the player selects an incorrect color, the game displays the final score, briefly changes the screen color to indicate failure, and allows the player to restart.

This project demonstrates core concepts of front-end web development, including DOM manipulation, event handling, arrays, functions, timers, and dynamic user interaction, making it an effective learning project for JavaScript programming.
